CS150 - Sample Final

Name: _____

Honor code:

You may use the following material on this exam:

- The final exam "cheat sheet" which I have provided

- The "matlab basics" handout (without any additional notes)

- Up to two pages of notes with 10 point font or larger (or comparable hand-written)

Beyond that, this exam is closed book, closed notes, closed computer, closed calculator, etc.

You do not need to include comments or constants in your code.
I AVOID DRINKING FOUNTAINS OUTSIDE BATHROOMS BECAUSE I'M AFRAID OF GETTING TRAPPED IN A LOOP.

http://www.xkcd.com/986/

For grading:

1: Odd and ends	18	
2: Matlab	10	
3: Dictionaries	9	
4: Recursion	13	
5: We've got problems	7	
6: Sequences	12	
Total	69	

1. **[18 points]** Odds and ends

   (a) **[5 points]** T/F: For each statement below, indicate whether the statement is true or false. If you make an assumption about something in the statement, please note it underneath your answer.

   _____ For all possible inputs insertion sort is faster than selection sort.

   _____ 01101 in binary is equal to 13.

   _____ '*' in R for vectors is equivalent to '.*' in Matlab for vectors.

   _____ If we typed the two first statements below, s would have the value shown below:
   ```
   >>> s = "this is a test"
   >>> s.upper()
   'THIS IS A TEST'
   >>> s
   'THIS IS A TEST'
   ```

   _____ For an $O(n^2)$ algorithm, if it takes 10 seconds to run on 1000 items we would expect it to take approximately 40 seconds on 2000 items.

(b) [**3 points**] Add the following two binary numbers: `01101101` with `00111101`. Make sure to show your work (i.e. carries, etc.).

(c) [**5 points**] Given the following code in a file called `my_file.py`:

```
# some code up here

if __name__ == "__main__":
    print "bananas " * 2
else:
    print "apples"[:-3]

print "End of " + __name__
```

What would happen if the file were run with the green arrow in Wing?

What would happen if we then typed `import my_file` in the python shell?

(d) [**5 points**] The `xor` (exclusive or) of two boolean values is `True` if either value is `True`, but is `False` if they are both `True` or both `False`. The following is the "truth table" for `xor`:

a	b	xor(a,b)
F	F	F
F	T	T
T	F	T
T	T	F

Write a function `xor` that calculates the exclusive or of two boolean variables. Remember to use good boolean style!

2. [**10 points**] Matlab

   (a) [**4 points**] If we initialized `x` in Matlab to be the following matrix:

```
10 4  3
1  7  15
6  4  2
```

What would be displayed by the following:

    i. `disp(x(:, 1))`

    ii. `disp(sum(x))`

    iii. `disp(sum(x > 5))`

    iv. `disp(sum(sum(x .* (x > 5)))`

   (b) [**6 points**] Write a Matlab function that takes a matrix as a parameter and returns the difference between the largest and smallest values in that matrix.

3. [**9 points**] Dictionaries

(a) [**6 points**] Write a function called `dictionary_add` that takes two dictionaries whose *values* are numbers and returns a dictionary containing the keys found in **both** dictionaries. The value associated with these keys should be the sum of the values in the two dictionaries. If a key does not occur in BOTH dictionaries, then it should not occur in the returned dictionary. For example:

```
>>> d1 = {"a":1, "b":2, "c":3}
>>> d2 = {"a":4, "c":5, "d": 6}
>>> dictionary_add(d1, d2)
{'a': 5, 'c': 8}
```

(b) [**3 points**] In one sentence, what does the following function do if `dict1` and `dict2` are dictionaries? Be concise, but precise.

```
def mystery(dict1, dict2):
    for key in dict1:
        if not key in dict2:
            return False

    return True
```

4. [**13 points**] Recursion

(a) [**5 points**] Draw what the following function would draw on the screen for the call
`mystery(80, 5)` assuming the turtle started at the center of the screen (0,0) and was
facing to the right. In addition, annotate your drawing with the final turtle location.

```
from turtle import *

def mystery(length, levels):
    if levels == 0:
        dot()
    else:
        forward(length)
        left(90)

        mystery(length/2, levels-1)

        right(90)
        backward(length)
```

(b) [**3 points**] What does the following function return for the input "CS class":

```
def mystery(s):
  if s == "":
    return s
  else:
    if s[0].isupper():
      return s[0].lower() + mystery(s[1:])
    else:
      return s[0].upper() + mystery(s[1:])
```

(c) [**5 points**] Write a function called **sum_squared** that takes a list of numbers as a parameter and returns the sum of the each of the numbers squared. For example, **sum_squared([1, 2, 3])** would return 14 (that is, $1*1 + 2*2 + 3*3=14$). If you write the function *recursively* you will receive up to 5 points. If do not use recursion you can only receive a maximum of 3.5 points.

5. **[7 points]** We've got problems...

   (a) **[4 points]** The following program expects two command-line arguments. The program is supposed to print the usage if the user doesn't supply exactly two arguments, or run the function my_function(...) if the user does supply two arguments. However, the program has **two** general problems. Fix the problems so that it works as expected. You don't have to rewrite the function, just mark-up the one below.

```
import sys

def my_function(a, b):
  # some function stuff

def print_usage():
  print "my_program.py <number> <number>"

number1 = sys.argv[0]
number2 = sys.argv[1]

if len(sys.argv) != 2:
  print_usage()
else:
  my_function(number1, number2)
```

   (b) **[3 points]** The following function attempts to check if a number is prime or not, but it has a mistake. Correct the function:

```
import math

def isprime(num):
    """Returns True if the input is a prime number, False otherwise"""
    for i in range(2, int(math.sqrt(num)+1)):
        if num % i == 0:
            return False
        else:
            return True
```
6. [**12 points**] Sequences

    (a) [**6 points**] Write a function called `unique` that takes a string as a parameter and returns `True` if all of the characters in the string are unique (i.e no repeats) or `False` if there are duplicate letters. You will only get partial credit if your function is not efficient.

(b) [**6 points**] Write a function `reverse_sentence` that takes a string representing a sentence and returns a new string where all the words in the sentence are in reverse order. You can assume a "word" is anything separated by a space. For example:

```
>>> reverse_sentence("this is a sentence")
'sentence a is this'
```

Have a great break!
