

Lecture 3: Representing Signed Integers

CS 105

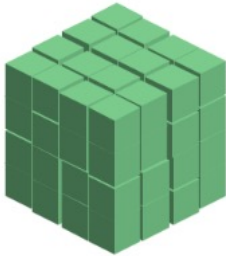

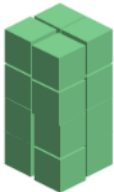

Fall 2023

Review: Binary Numbers

Representing Signed Integers

- Option 1: sign-magnitude
 - One bit for sign; interpret rest as magnitude
 - $Signed(x) = (-1)^{x_{w-1}} \cdot \sum_{i=0}^{w-2} x_i \cdot 2^i$

+/-	64 (2^6)	32 (2^5)	16 (2^4)	8 (2^3)	4 (2^2)	2 (2^1)	1 (2^0)
—							
0	0	0	0	0	1	0	1
1	0	0	0	0	1	0	1
1	1	1	1	1	1	1	1

Example: Three-bit integers

Base-10	unsigned	signed
7	111	
6	110	
5	101	
4	100	
3	011	011
2	010	010
1	001	001
0	000	000
-1		111
-2		110
-3		101
-4		100

- For signed ints:
 - high-order bit is 0 for pos values, 1 for neg
 - 000...0 is 0
 - 111...1 is -1
 - same representation as unsigned for numbers that can be represented with both
 - $\sim x + 1 == -1 * x$

Exercise 1: Signed Integers

Assume an 8 bit (1 byte) signed integer representation:

- What is the binary representation for 47?
- What is the binary representation for -47?
- What is the number represented by 10000110?
- What is the number represented by 00100101?

Casting between Numeric Types

- Casting from shorter to longer types preserves the value
- Casting from longer to shorter types drops the high-order bits
- Casting between signed/unsigned types preserves the bits (it just changes the interpretation)
- Implicit casting occurs in assignments and parameter lists. In mixed expressions, signed values are implicitly cast to unsigned
 - Source of many errors!

Exercise 2: Casting

- Assume you have a machine with 6-bit integers/3-bit shorts
- Assume variables: `int x = -17; short sy = -3;`
- Complete the following table

Expression	Decimal	Binary
<code>x</code>	-17	
<code>sy</code>	-3	
<code>(unsigned int) x</code>		
<code>(int) sy</code>		
<code>(short) x</code>		

When to Use Unsigned

- Rarely
- When doing multi-precision arithmetic, or when you need an extra bit of range ... but be careful!

```
for (unsigned int i = cnt-2; i >= 0; i--){  
    a[i] += a[i+1];  
}
```

Arithmetic Logic Unit (ALU)

- circuit that performs bitwise operations and arithmetic on integer binary types

Bitwise vs Logical Operations in C

- Bitwise Operators `&`, `|`, `~`, `^`
 - View arguments as bit vectors
 - operations applied bit-wise in parallel
- Logical Operators `&&`, `||`, `!`
 - View 0 as “False”
 - View anything nonzero as “True”
 - Always return 0 or 1
 - **Early termination**
- Shift operators `<<`, `>>`
 - Left shift fills with zeros
 - For signed integers, right shift is arithmetic (fills with high-order bit)

Exercise 3: Bitwise vs Logical Operations

- What is the binary representation of each of the following expressions? Assume signed char data type (one byte).

1. $\sim(-30)$

2. $-30 \mid 21$

3. $-30 \mid\mid 21$

4. $-30 \ll 2$

5. $-30 \gg 2$

Addition Example

- Compute $5 + -3$ assuming all ints are stored as four-bit signed values

$$\begin{array}{r} 1 1 \\ 0 1 0 1 \\ + 1 1 0 1 \\ \hline 0 0 1 0 \end{array} = 2 \text{ (Base-10)}$$

Exactly the same as unsigned numbers!

... but with different error cases

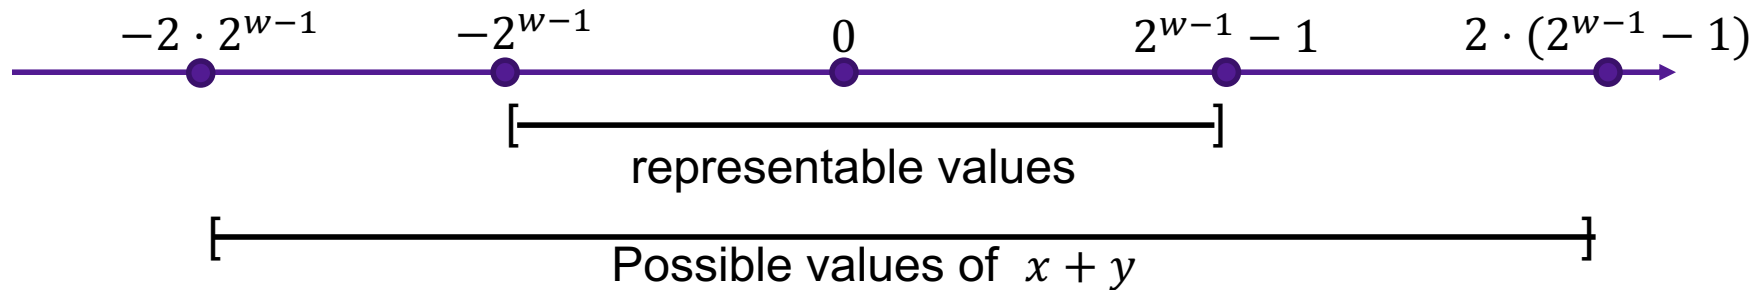

Addition/Subtraction with Overflow

- Compute $5 + 6$ assuming all ints are stored as four-bit signed values

$$\begin{array}{r} 1 \\ 0101 \\ + 0110 \\ \hline 1011 \end{array} = -5 \text{ (Base-10)}$$

Error Cases

- Assume w -bit signed values

- $$x + \overset{t}{w}y = \begin{cases} x + y - 2^w & \text{(positive overflow)} \\ x + y & \text{(normal)} \\ x + y + 2^w & \text{(negative overflow)} \end{cases}$$

- overflow has occurred iff $x > 0$ and $y > 0$ and $x + \overset{t}{w}y < 0$
or $x < 0$ and $y < 0$ and $x + \overset{t}{w}y > 0$

Exercise 4: Binary Addition

- Given the following 5-bit signed values, compute their sum and indicate whether or not an overflow occurred

x	y	x+y	overflow?
00010	00101		
01100	00100		
10100	10001		

Multiplication Example

- Compute 3×2 assuming all ints are stored as four-bit signed values

$$\begin{array}{r} 0011 \\ \times 0010 \\ \hline 0000 \\ + 00110 \\ \hline 0110 \end{array} = 6 \text{ (Base-10)}$$

Exactly like unsigned multiplication!
... except with different error cases

Multiplication Example

- Compute 5×2 assuming all ints are stored as four-bit signed values

$$\begin{array}{r} 0101 \\ \times 0010 \\ \hline 0000 \\ + 01010 \\ \hline 1010 \end{array} = -6 \text{ (Base-10)}$$

Error Cases

- Assume w -bit unsigned values

- $x *_w^t y = U2T((x \cdot y) \bmod 2^w)$

Exercise 5: Binary Multiplication

- Given the following 3-bit signed values, compute their product and indicate whether or not an overflow occurred

x	y	x*y	overflow?
100	101		
010	011		
111	010
