## **CS105 – Computer Systems**

Spring 2023

## Week 5: Buffer Overflow Attacks SOLUTION

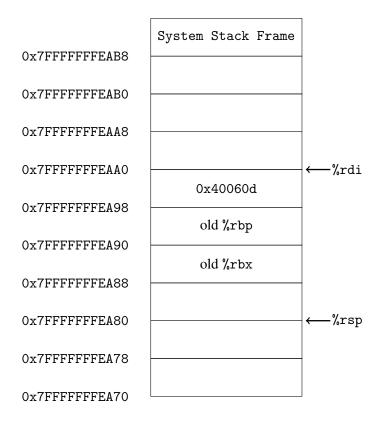

February 20-22, 2023

Tired of being thwarted by meddling 105 students, Dr. Evil tracks down an unsuspecting student who has put off taking CS 105 and convinces them to run the following program.

Consider the following C program and the corresponding machine code: #include <stdio.h>

```
int isPosInt(char * s){
                                       0x4005fc <main>:
    char * p = s;
                                           0x4005fc <+0>: sub
                                                                  $0x18, %rsp
    while(*s != '\n'){
                                                                  $0xc, %esi
                                           0x400600 <+4>: mov
        if(*s < 48 || *s > 57){
                                           0x400605 <+9>: mov
                                                                  %rsp,%rdi
                                                                  0x4005c6 <getPosInt>
            return 0;
                                           0x400608 <+12>: callq
        }
                                                                  %rsp,%rdi
                                           0x40060d <+17>: mov
                                           0x400610 <+20>: callq 0x400470 <puts@plt>
   }
                                           0x400615 <+25>: mov
                                                                  $0x0, %eax
   return 1;
                                           0x40061a <+30>: add
                                                                  $0x18, %rsp
}
                                           0x40061e <+34>: retq
void getPosInt(char * s, int n){
                                       0x4005c6 <getPosInt>:
    int done = 0;
                                           0x4005c6 <+0>: push
                                                                  %rbp
   while(!done){
                                           0x4005c7 < +1>: push
                                                                  %rbx
        gets(s, stdin);
                                           0x4005c8 <+2>: sub
                                                                  $0x8,%rsp
        done = isPosInt(s);
                                                                  %rdi,%rbx
                                           0x4005cc <+6>: mov
   }
                                                                  %esi,%ebp
                                           0x4005cf <+9>: mov
}
                                                                  $0x0, %eax
                                           0x4005d1 <+11>: mov
                                           0x4005d6 < +16>: jmp
                                                                  0x4005f1 <getPosInt+43>

                                                                  0x4005d8 <getPosInt+18>
                                           0x4005f5 < +47>: add
                                                                  $0x8,%rsp
                                           0x4005f9 < +51>: pop
                                                                  %rbx
                                           0x4005fa <+52>: pop
                                                                  %rbp
                                           0x4005fb <+53>: retq
                                       0x4005a6 <isPosInt>:
                                           // more assembly code
```

1. Below is a diagram of the stack at the beginning of function main (that is, when %rip = 0x4005fc).

- (a) Draw a detailed diagram of the stack immediately before the function gets is called (that is, when %rip = 0x4005e4). If you cannot determine from the provided information what value is stored at some address, enter a ? in the corresponding box. Assume that the initial value in register %rbp is 0. Assume that initial value in register %rbx is 0x400620.
- (b) Add arrows to the above diagram to show the current values stored in %rsp and %rdi
- Assume that Dr. Evil has somehow included an evil function located in memory at address 0x406147.
   Construct an example exploit string that would cause the evil function to get executed after main returns. Assume the machine is little endian.

## AAAAAAAAAAAAAAAAAAAAAAAGa@

Note that the 24 A characters constitute 24 bytes of filling, G is the character with the ascii encoding 0x47, a is the character with the ascii encoding 0x61 and @ is the character with the ascii encoding 40. The bytes of the address of the evil function are reversed because the machine is little-endian.

3. Maybe Dr. Evil was unable to include his evil function in the code. Assume that he instead enters a carefully constructed exploit string so that at the point immediately before main returns, the state of the stack is shown below.

07FFFFFFFFF	0a	00	00	00	00	00	00	00
0x7FFFFFFEB10	1e	06	40	00	00	00	00	00
0x7FFFFFFEB08	47	47	47	47	47	47	47	47
0x7FFFFFFFEB00	47	47	47	47	47	47	47	47
0x7FFFFFFFEAF8	42	6f	6f	6d	21	00	00	00
0x7FFFFFFFEAF0	0d	06	40	00	00	00	00	00
0x7FFFFFFFEAE8	61	68	61	68	61	68	61	00
0x7FFFFFFFEAE0	47	47	47	47	4d	77	61	68
0x7FFFFFFFEAD8			47					
0x7FFFFFFFEAD0	<u> </u>							
0x7FFFFFFFEAC8			40					
0x7FFFFFFFEAC0	dc	ea	ff	ff	ff	7f	00	00
0x7FFFFFFFEAB8	2a	04	40	00	00	00	00	00

You should interpret the sequence of bytes in each box as as the hex-encoding of the eight byte sequence starting at the address labeled at the bottom of the box and ending one byte before the address labeled at the top of the box. So, for example, the byte at address 0x7FFFFFFFEAB8 is 2a and the byte at 0x7FFFFFFFEABF is 00

**Hint:** You may assume the Pomona server is a little-Endian machine.

**Hint:** Observe that the address in %rsp immediately before main returns will be 0x7FFFFFFEAB8.

Assume that the byte at address 0x40042a is 0x5f (the byte-level encoding of pop %rdi) and the byte at address 0x40042b is 0xc3 (the byte-level encoding of ret). A table of potentially useful ASCII encoding is given below.

(a) Fill in the table below with the values in each of the following registers when %rip stores each of the values. Each line of the table should correspond to one assembly instruction (so line 1 will describe the state of the registers after the instruction retq from line 0 completes, line 2 will describe the state of the registers after the instruction from line one completes, etc.) The initial line (immediately before the main function returns) has been filled out to help you get started. Treat any function calls as one instruction (i.e., "step over" them same as nexti would in gdb).

**Hint:** Remember that %rip stores the address of the next instruction to execute.

**Hint:** For addresses on the stack, it's fine to just use the last two bytes (e.g., eab8 instead of 0x7fffffffeab8).

	%rip	(%rip)	%rsp	%rdi	
0	0x40061e	retq	0x7ffffffffeab8	0x7ffffffffeab8	
1	0x40042a	pop %rdi	0x7ffffffffeac0	0x7fffffffeab8	
2	0x40042b	ret	0x7ffffffffeac8	0x7ffffffffeadc	
3	0x400610	callq puts	0x7ffffffffead0	0x7ffffffffeadc	
4	0x400615	mov \$0x0, %eax	0x7ffffffffead0	?	
5	0x40061a	add \$0x18, %rsp	0x7ffffffffead0	?	
6	0x40061e	ret	0x7ffffffffeae8	?	
7	0x40060d	mov %rsp, %rdi	0x7ffffffffeaf0	?	
8	0x400610	callq puts	0x7ffffffffeaf0	0x7ffffffffeaf0	
9	0x400615	mov \$0x0, %eax	0x7fffffffeaf0	?	
10	0x40061a	add \$0x18, %rsp	0x7ffffffffeaf0	?	
11	0x40061e	ret	0x7fffffffeb08	?	

(b) What gets printed after the main function returns?

**Hint:** puts prints the string passed in as its first argument.

Mwahahaha

Boom!
